## pH indicators---how they work!

pH indicators are either weak acids or weak bases---that are different in color (change in absorbance) in protonated vs. unprotonated form!

They are used at very low concentrations ----to "indicate" the pH of the solution----with the pH generally being controlled by other components!!

Yellow (Y)
Bromocresol green

Blue ( $\mathrm{B}^{-}$)

Equilibrium for indicator species: Hin <------> $\mathrm{H}^{+}+\mathrm{In}^{-}$

$$
\begin{aligned}
& K_{H I n}=\frac{\left[H^{+}\right]\left[I^{-}\right]}{[H I n]} \\
& p H=p K_{H I n}+\log \frac{\left[I n^{-}\right]}{[H I n]}
\end{aligned}
$$

for bromocrescol green----In- is blue and HIn is
at pH 4.7 (the $\mathrm{pK}_{\mathrm{a}}$ ) ---have half in blue form, and half in yellow formget a green color!!

Typically---when [Hin]/[In-] > 10 ; color of solution will be color of Hin species; when [ In -] / [ Hin ] > 10 ; color of solution will be color of $\mathrm{In}^{-}$species!
-By using very low concentrations of indicator---we can get very sharp change in color at equivalence points in pH titrations!

Example of indicator that is diprotic---two different pKa values three different species possible--with three different colors!

at $\mathrm{pH} \ll 0.7$---solution will be red
from pH approx. $0 . ; 7$-2.7; solution will look orange from $\mathrm{pH} 2.7--7.9$; solution will be from pH 7.9 - 9.9 ; solution will be green at $\mathrm{pHs}>9.9$; solution will be blue!

Acid-Base Titrations---predicting shape and pH at given points along a titration curve!

## Different types ---

a) titration of strong acid with strong base or vica versa!
b) titration of weak acid with strong base
c) titration of weak base with strong acid

Lets start with strong acid/strong base situation--
we know that $\mathrm{H}^{+}+\mathrm{OH}^{-}----->\mathrm{H}_{2} \mathrm{O} \quad \mathrm{K}=1 / \mathrm{K}_{\mathrm{w}}=10^{14}$---very favorable reaction---rxn goes to completion!

So if we start with base in solution---and add acid---for every proton we add---it will react with hydroxide ion to form water---until there are no more excess hydroxide ions available-equiv. point $=\mathbf{p H} 7.0$

3-regions in titration curve-- 1) before equiv. point; 2) at equiv. point;
3) after equiv. point!

titration of 50 mL of 0.02 M KOH with 0.1 M HBr---
need 1 mmole of HBr to neutralize all the base ( $50 \mathrm{~mL} \mathrm{x} 0.02=1 \mathrm{mmole}$ )
therefore at equiv. point-$\mathrm{M}_{\mathrm{HBr}} \times \mathrm{V}_{\mathrm{HBr}}=1 \mathrm{mmole}$
$0.1 \times \mathrm{V}_{\mathrm{HBr}}=1 \mathrm{mmole}$
$\mathrm{V}_{\mathrm{HBr}}=\mathrm{V}_{\mathrm{e}}=10 \mathrm{~mL}$

Lets see what pH is at various points---via calculations---
when no acid added:
0.02 M KOH only present; $\left[\mathrm{OH}^{-}\right]=0.02 \mathrm{M}$;
$\left[\mathrm{H}^{+}\right]=10^{-14} / 0.02=5 \times 10^{-13} \mathrm{M}$
$\mathrm{pH}=-\log \left[\mathrm{H}^{+}\right]=\mathbf{1 2 . 3 0}$
when 3 mL of titrant added:
$3 \mathrm{ml} \times 0.1 \mathrm{M}=0.3$ mmoles of acid---means that you decrease
total amount of $\mathrm{OH}^{-}$by 0.3 mmoles---
therefore: $(1.0$ mmole -0.3 mmoles $)=0.7 \mathrm{mmoles}^{\mathrm{OH}}{ }^{-}$still present in solution---but now the total volume $=\mathbf{5 0}+\mathbf{3 = 5 3} \mathbf{~ m L}$

$$
\begin{aligned}
& {\left[\mathrm{OH}^{-}\right]=0.7 / 53=0.013 \mathrm{M} ;\left[\mathrm{H}^{+}\right]=10^{-14} / 0.013=7.69 \times 10^{-13}} \\
& \mathrm{pH}=-\log 7.69 \times 10^{-13}=12.11
\end{aligned}
$$

when 9.90 mL of acid added:
$9.90 \times 0.1 \mathrm{M}=0.99$ mmoles of acid; thus $\mathrm{OH}^{-}$left $=1.0-0.99=0.01$ mmoles
$\left[\mathrm{OH}^{-}\right]=0.01 / 59.9 \mathrm{~mL}^{-}=1.67 \times 10^{-4}$
$\left[\mathrm{H}^{+}\right]=10^{-14} / 1.67 \times 10^{-4}=5.99 \times 10^{-11}$; therefore $\mathbf{p H}=\mathbf{1 0 . 2 2}$
when 10.0 mL of acid added (equivalence point):
$10 \mathrm{~mL} \times 0.1 \mathrm{M}=1.0 \mathrm{mmoles}-$; no more $\mathrm{OH}^{-}$from the base is present at this point---only $\mathrm{OH}^{-}$is from autoprotolysis of water!--$\left[\mathrm{OH}^{-}\right]=10^{-7} ;\left[\mathrm{H}^{+}\right]=10^{-7} ; \mathbf{p H}=\mathbf{7 . 0 0}$
when 10.1 mL of acid added---just beyond equiv. point:
$10.1 \mathrm{~mL} \times 0.1 \mathrm{M}=1.01 \mathrm{mmoles}$; excess $\mathrm{H}^{+}$by 0.01 mmoles $\left[\mathrm{H}^{+}\right]=0.01 \mathrm{mmole} / 60.1 \mathrm{~mL}=1.66 \times 10^{-4} \mathrm{M}$ therefore: $\mathrm{pH}=-\log \left(1.66 \times 10^{-4}\right)=\mathbf{3 . 7 8}$
when 11 mL of acid added---far beyond equiv. point:
$11 \mathrm{~mL} \times 0.1 \mathrm{M}=1.1 \mathrm{mmoles}$; excess $\mathrm{H}^{+}$by 0.1 mmoles
$\left[\mathrm{H}^{+}\right]=0.1 \mathrm{mmole} / 61.0 \mathrm{~mL}=1.64 \times 10^{-3} \mathrm{M}$
$\mathrm{pH}=-\log \left(1.64 \times 10^{-3}\right)=\mathbf{2 . 7 9}$

For titration of strong acid with base--the same exact approach is taken to find the pH at various points along the titration curve! Sample problem: Find the pH when 12.75 mL of 0.0501 M NaOH have been added to 25.00 mL of $0.0506 \mathrm{M} \mathrm{HClO}_{4}$ !

- how many moles of $\mathbf{H C l O}_{4}$ originally present?
$25 \mathrm{~mL} \times 0.0506 \mathrm{M}=\mathbf{1 . 2 6 5}$ mmoles
- after 12.75 mL base--how many moles of base?
$12.75 \mathrm{~mL} \times 0.0501 \mathrm{M}=\mathbf{0 . 6 3 9} \mathbf{~ m m o l e s}$ of base---so there must be excess acid still left!
How much acid left? $1.265-0.639=\mathbf{0 . 6 2 6} \mathbf{~ m m o l e s}$
What pH ? ; $\left[\mathrm{H}^{+}\right]=\mathbf{0 . 6 2 6}$ mmoles $/ 37.75 \mathrm{~mL}=\mathbf{0 . 0 1 6 6} \mathrm{M}$ $\mathbf{p H}=-\log (0.0166)=\mathbf{1 . 7 8} \quad$ total volume

Find pH after 50 mL of base added?--50 mL x $0.0501 \mathrm{M}=2.505 \mathrm{mmole}$ now have excess base- : 2.505-1.265 $=1.24$ mmoles NaOH excess $\left[\mathrm{OH}^{-}\right]=1.24$ mmoles $/ 75 \mathrm{~mL}=0.0165 \mathrm{M} ;\left[\mathrm{H}^{+}\right]=10^{-14} / 0.0165=$ $\left[\mathrm{H}^{+}\right]=6.06 \times 10^{-13} ; \mathbf{p H}=\mathbf{1 2 . 2 2}$

Titration of weak acid with strong base:

$$
\mathrm{HA}+\mathrm{OH}^{-}----->\mathrm{H}_{2} \mathrm{O}+\mathrm{A}^{-} \quad \mathrm{K}^{\prime} ?=1 / \mathrm{K}_{\mathrm{b}} \text { for } \mathrm{A}^{-}
$$

let's say $\mathrm{pK}_{\mathrm{a}}$ of $\mathrm{HA}=6.15 ; \mathrm{K}_{\mathrm{a}}=7.08 \times 10^{-7}$
What is $\mathrm{K}_{\mathrm{b}}$ for $\mathrm{A}^{-}$? recall--- $\mathrm{K}_{\mathrm{b}}=10^{-14} / \mathrm{K}_{\mathrm{a}(\mathrm{HA})}$ then $\mathrm{K}_{\mathrm{b}}=1.41 \times 10^{-8}$----for rxn in opposite in direction of abovetherefore $K^{\prime}=1 /\left(1.41 \times 10^{-8}\right)=\mathbf{7 . 1} \times \mathbf{1 0}^{7}$ since K ' is large---neutralization reaction goes completely to right

Let's say we have 50.00 mL of 0.0200 M of HA to start in solution!
how much volume of 0.1000 M NaOH is needed to reach equiv. point? $50.00 \mathrm{~mL} \times 0.0200 \mathrm{M}=\mathbf{1} \mathbf{~ m m o l e}$ of acid present---need $\mathbf{1} \mathbf{~ m m o l e}$ of base to reach equivalence point---
Therefore--- $0.1000 \mathrm{M} \mathrm{x}_{\text {base }}=1 \mathrm{mmole} ; \mathbf{V}_{\text {base }}=\mathbf{1 0} \mathbf{~ m L}$

Titration of weak acid with strong base:

$$
\mathrm{HA}+\mathrm{OH}^{-}----->\mathrm{H}_{2} \mathrm{O}+\mathrm{A}^{-} \quad \mathrm{K}^{\prime} ?=1 / \mathrm{K}_{\mathrm{b}} \text { for } \mathrm{A}^{-}
$$

let's say $\mathrm{pK}_{\mathrm{a}}$ of $\mathrm{HA}=6.15 ; \mathrm{K}_{\mathrm{a}}=7.08 \times 10^{-7}$
What is $\mathrm{K}_{\mathrm{b}}$ for $\mathrm{A}^{-}$? recall--- $\mathrm{K}_{\mathrm{b}}=10^{-14} / \mathrm{K}_{\mathrm{a}(\mathrm{HA})}$ then $\mathrm{K}_{\mathrm{b}}=1.41 \times 10^{-8}$----for rxn in opposite in direction of abovetherefore $K^{\prime}=1 /\left(1.41 \times 10^{-8}\right)=\mathbf{7 . 1} \times \mathbf{1 0}^{7}$ since K ' is large---neutralization reaction goes completely to right

Let's say we have 50.00 mL of 0.0200 M of HA to start in solution!
how much volume of 0.1000 M NaOH is needed to reach equiv. point? $50.00 \mathrm{~mL} \times 0.0200 \mathrm{M}=\mathbf{1} \mathbf{~ m m o l e}$ of acid present---need $\mathbf{1} \mathbf{~ m m o l e}$ of base to reach equivalence point---
Therefore--- $0.1000 \mathrm{M} \mathrm{x}_{\text {base }}=1 \mathrm{mmole} ; \mathbf{V}_{\text {base }}=\mathbf{1 0} \mathbf{~ m L}$

## four regions of the titration curve----

1) no base added; what is starting pH ?

Calculate like weak acid problem- for $\mathrm{F}=0.0200 \mathrm{M}$ with

$$
\mathrm{K}_{\mathrm{a}}=7.08 \times 10^{-7}
$$

$$
\mathrm{x}^{2} /(0.0200-\mathrm{x})=7.08 \times 10^{-7} ; \mathrm{x}=1.19 \times 10^{-4}=\left[\mathrm{H}^{+}\right] ; \mathbf{p H}=\mathbf{3 . 9 3}
$$

2) initial addition of base to titrate weak acid---becomes buffer system calculation problem----some of $\mathrm{HA}+\mathrm{OH}^{-}----->\mathrm{A}^{-}+\mathrm{H}_{2} \mathrm{O}$ For example---say 2 mL of $0.1000 \mathrm{M} \mathrm{NaOH}---$ produce $2 \mathrm{~mL} \times 0.1000 \mathrm{M}=0.2 \mathrm{mmoles}$ of $\mathrm{A}^{-}$ starting $\mathrm{HA}=1$ mmole ; therefore after 2 mL of NaOH solution possesses $1.000-0.200=0.800$ mmoles HA and 0.2 mmoles A- $^{-}$

Can use HH eqn to calculate pH in this region of titration curve-$\mathbf{p H}=\mathrm{pK}_{\mathrm{a}}+\log \left(\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]\right)=6.15+\log (0.2 / 0.8)=\mathbf{5 . 5 5}$ note: don't need to calculate conc. of $\mathrm{A}^{-}$and HA--only need mmoles for numerator and demoninator!
when you have added 5 mL of titrant ---then $\mathrm{V}_{\text {base }}=1 / 2 \mathrm{~V}_{\text {eq }}$ Exactly $1 / 2$ of the HA has been titrated----
This means that $[\mathrm{HA}]=\left[\mathrm{A}^{-}\right] \sim=1 / 2 \mathrm{~F}$--the initial conc. of HA

Special situation---since $\mathrm{pH}=\mathrm{pK}_{\mathrm{a}}+\log \left(\left[\mathrm{A}^{-}\right] /[\mathrm{HA}]\right)$---but log term -----> 0 since $[\mathrm{HA}]=\left[\mathrm{A}^{-}\right] ; \mathbf{p H}=\mathbf{p K} \mathbf{a}=\mathbf{6 . 1 5}$
3. At equivalence point ( 10 mL of NaOH added):

All the HA ------> A- and water----Hence the pH at equiv. point is a weak base problem-----A- $+\mathrm{H}_{2} \mathrm{O}$ <-----> $\mathrm{HA}+\mathrm{OH}^{-}$ must calculate [ $\mathrm{OH}^{-}$] using $\mathrm{K}_{\mathrm{b}}$ value---
But-- initial $F$ concentration of $\mathrm{A}^{-}$is less than initial [HA] due to dilution by titrant volume!
$\left[\mathrm{A}^{-}\right]_{\mathrm{eq}}=1 \mathrm{mmole} / 60 \mathrm{~mL}=\mathbf{0 . 0 1 6 6 7} \mathbf{M}=\mathbf{F}^{\prime}$ (new formal conc.)
initial
total vol. at equiv. point!
$\mathrm{K}_{\mathrm{b}}$ for $\mathrm{A}^{-}=1.41 \times 10^{-8}=\mathrm{x}^{2} /\left(\mathrm{F}^{\prime}-\mathrm{x}\right) \quad ; \mathrm{F}^{\prime}=0.01667 \mathrm{M}$

$$
\begin{aligned}
& \mathrm{X}=1.53 \times 10^{-5}=\left[\mathrm{OH}^{-}\right] ;\left[\mathrm{H}^{+}\right]=10^{-14} /\left(1.53 \times 10^{-5}\right)=6.54 \times 10^{-10} \\
& \mathbf{p H}=-\log \left(\mathbf{6 . 5 4} \times \mathbf{1 0}^{-\mathbf{1 0}}\right)=\mathbf{9 . 1 8}=\mathbf{p H} \text { at equiv. point }
\end{aligned}
$$

4) pH when there is excess strong base-----; can assume contribution from weak base $\mathrm{A}^{-}$is negligible!
e.g. 11 mL of $\mathbf{N a O H}$ added; total volume now $=61.00 \mathrm{~mL}$ excess base $=1 \mathrm{~mL} \times 0.1000 \mathrm{M}=0.1 \mathrm{mmole}$;
Therefore: $0.1000 / 61.00=0.0016 \mathrm{M}=\left[\mathrm{OH}^{-}\right]$ thus-- $\left[\mathrm{H}^{+}\right]=10^{-14} / 0.0016=6.25 \times 10^{-12} ; \mathbf{p H}=\mathbf{1 1 . 2 0}$

This is the actual titration curve for 0.02 M HA with $\mathrm{pKa}=6.15$ with 0.1000 M NaOH
---we calculated several of the points along the way--on the previous pages!!

Titration of weak base with strong acid---Analogous treatment to titration of weak acid with strong base!!

## Titration reaction:

$$
\begin{aligned}
& \text { Pyridine }(\mathrm{B}) \\
& K_{\mathrm{b}}=1.69 \times 10^{-9} \quad \mathrm{~K}_{\mathrm{a}}=5.92 \times 10^{-6}
\end{aligned}
$$

$\mathrm{BH}^{+}$
e.g.--- 25.00 mL of 0.08364 M pyridine titrated with 0.1067 M HCl mmoles pyridine base $=0.08364 \times 25.00=\mathbf{2 . 0 9 1} \mathbf{~ m m o l e s}$ at equiv. point:
$\mathrm{V}_{\mathrm{HCl}} \times 0.1067 \mathrm{M}=25.00 \mathrm{~mL} \times 0.08364 ; \mathrm{V}_{\mathrm{e}(\mathrm{HCl})}=\mathbf{1 9 . 6 0} \mathbf{~ m L ~ H C l}$

## What is $\mathbf{p H}$ after 4.63 mL of acid added:

mmoles acid $=4.63 \times 0.1067=\mathbf{0 . 4 9 4 0}$ mmole of Pyridinium cation; therefore free base left $=2.091-0.4940=\mathbf{1 . 5 9 7} \mathbf{m m o l e}$ Pyridine left thus $\mathbf{p H}=\mathbf{p K}_{\mathbf{a}}+\log \left([\mathbf{p y r}] /\left[\left[\mathbf{H p y r}^{+}\right]\right)=5.23+\log (1.597 / 0.4940)=\right.$ $\mathbf{p H}=5.74$

What would be pH at equivalence point?

This is weak acid problem---all of the pyridine converted to $\mathrm{Hpyr}^{+}$; -started with 2.091 mmoles pyridine---will have 2.091 mmoles of pyridinium ion at equivalence point!

$$
\begin{aligned}
& \mathrm{K}_{\mathrm{a}}=5.92 \times 10^{-6}=\mathrm{x}^{2} /\left(\mathrm{F}^{\prime}-\mathrm{x}\right) \\
& \mathrm{F}^{\prime}=2.091 \text { mmoles } /(25.0 \mathrm{~mL}+19.6 \mathrm{~mL})=0.0469 \mathrm{M} \mathrm{Hpyr}^{+} \\
& \mathrm{x}_{1}=1.67 \times 10^{-4} ; \quad \mathrm{x}_{2}(\text { second. approx. })=1.66 \times 10^{-4}=\left[\mathrm{H}^{+}\right] \\
& \mathbf{p H}=\mathbf{3 . 7 8}
\end{aligned}
$$

note: pH at equivalence point is quite low--why? ---because pyridine is very weak base!!---if you calculated pH at start of titration what would it be? $1.69 \times 10^{-9}=\mathrm{x}^{2} /(\mathrm{F}-\mathrm{x}) ; \mathrm{F}=0.08364$

$$
\begin{gathered}
\mathrm{x}=\left[\mathrm{OH}^{-}\right]=1.19 \times 10^{-5} ;\left[\mathrm{H}^{+}\right]=8.40 \times 10^{-10} \\
\mathbf{p H}=\mathbf{9 . 0 8}
\end{gathered}
$$

Detecting end points!---use of indicators
-choose indicator that has $\mathrm{pK}_{\mathrm{a}}$ near the equivalence point pH of for titration---so that color change occurs in steepest region of titration curve!

- always use small amount of indicator---since they are also acids and bases---hence using high concentrations will consume analyte or titrant!
titration of weak base with
$\mathrm{pK}_{\mathrm{b}}=5.00$ with ( 100 mL of 0.0100 M ) with 0.0500 M HCl

With indicators--can only see pH change at end point of titration

Use pH electrode to monitor pH of solution throughout titration

End point/equivalence point can be determined by either first or second derivative method!
slope $=\Delta \mathrm{pH} / \Delta \mathrm{vol}=1$ st derivative
second deriv $=\frac{\Delta(\Delta p H / \Delta V)}{\Delta V}$
endpoint $=$ volume at which
second deriv. goes to 0 after inflection
blow-up of second derivative plot near equiv. point!

Can model and predict complete titration of weak base with strong acid---or weak acid with strong base! Results in equations that can be put into Excel spread sheet!
for weak acid titrated by strong base:

$$
\begin{aligned}
& \phi=\frac{C_{b} V_{b}}{C_{a} V_{a}}=\frac{\alpha_{A^{-}}-\frac{\left[\mathrm{H}^{+}\right]-\left[\mathrm{OH}^{-}\right]}{C_{a}}}{1+\frac{\left[\mathrm{H}^{+}\right]-\left[O H^{-}\right]}{C_{b}}} \\
& \alpha_{\mathrm{A}^{-}}=\text {fraction of HA in } \mathrm{A}^{-} \text {form! } \\
& \text { for weak base titrated by strong acid: } \\
& \phi=\frac{C_{a} V_{a}}{C_{b} V_{b}}=\frac{\alpha_{B H^{+}}-\frac{\left[H^{+}\right]-\left[\mathrm{OH}^{-}\right]}{C_{b}}}{1+\frac{\left[H^{+}\right]-\left[O H^{-}\right]}{C_{a}}} \\
& \text { where: } \quad \alpha_{A^{-}}=\frac{K_{a}}{\left[H^{+}\right]+K_{a}} \\
& \phi=\text { fraction of way to } \\
& \text { equivalence point } \\
& \mathrm{C}_{\mathrm{b}}=\text { conc. of base } \\
& \mathrm{C}_{\mathrm{a}}=\text { conc. of acid } \\
& \mathrm{V}_{\mathrm{a}}=\text { volume of acid } \\
& \mathrm{V}_{\mathrm{b}}=\text { volume of base } \\
& \alpha_{B H^{+}}=\frac{\left[H^{+}\right]}{\left[H^{+}\right]+K_{a\left(B H^{+}\right)}}
\end{aligned}
$$

example calculated curves for titration of acids with strong base--
note: as strength of acid decreases---end points are not sharp, and would be difficult to obtain!
obtain curves by putting in different pH values in eqn (then can calc. $\alpha,\left[\mathrm{OH}^{-}\right]$, etc.) and finally $\mathrm{V}_{\mathrm{b}}$ values for x -axis!
